- Revised RQ: Is there a correlation between vitamin D levels and the functionality of the MS microbiome in terms of disease severity
    - Try to avoid causality
    - Test if treatment vs. no treatment is a confounding variable
- X-axis as vitamin D levels
- Y-axis as alpha-rarefraction
- Categorize by “no vitamin D group” and “vitamin D group”
- Aims for research project
    - 3-4 aims
    - Breakdown RQ to achievable goals:
        - Determine if vitamin D affects diversity in microbiome
            - ie. alpha/beta diversity analysis, filtering steps, group subsetting
        - Differential species analysis, indicator species, etc.
            - Indicator = species present in one group but not other
            - Differential = species that are more different compared to both groups (still present in both)
        - Look at functionality of microbiome
            - Picrust
        - Can we predict MS severity based on vitamin D intake?
- Can start writing on methods and research purpose for research project
- Could run stratified picrust
    - Need to install
- Make R graphs look good
-
